

Government College of Engineering, Jalgaon

Department of Computer Engineering

Experiment No: 10

Subject:CO310U (Application programming Lab)

Sem:V(Odd)

PRN NO:2041024

Class:T.Y. B.Tech

Academic Year:2020-21

Date of Performance:

Date of Completion:

Aim: Write a program to draw a form using GUI components to accept details from a customer for a bank.

Required Software: OpenJDK version "1.8.0_131"

OpenJDK Runtime Environment (build 1.8.0_131-8u131-b11-2ubuntu1.16.04.3-b11)

OpenJDK 64-Bit Server VM (build 25.131-b11, mixed mode)

Java Compiler Version - JAVAC 1.8.0_131

Theory:

The AWT contains numerous classes and methods that allow you to create and manage windows. It is also the foundation upon which Swing is built. In this experiment, you will learn how to create and manage windows, manage fonts, output text, and utilize graphics, pushbuttons, supported by the AWT. It also explains further aspects of Java's event handling mechanism..Although a common use of the AWT is in applets, it is also used to create stand-alone windows that run in a GUI environment, such as Windows.

AWT Classes

The AWT classes are contained in the java.awt package. It is one of Java's largest packages. Fortunately, because it is logically organized in a top-down, hierarchical fashion, it is easier to understand and use than you might at first believe. Figure shows JAVA AWt hierarchy.

Container

The Container is a component in AWT that can contain other components like buttons, text fields, labels etc. The classes that extend Container class are known as containers such as Frame, Dialog and Panel.

Window

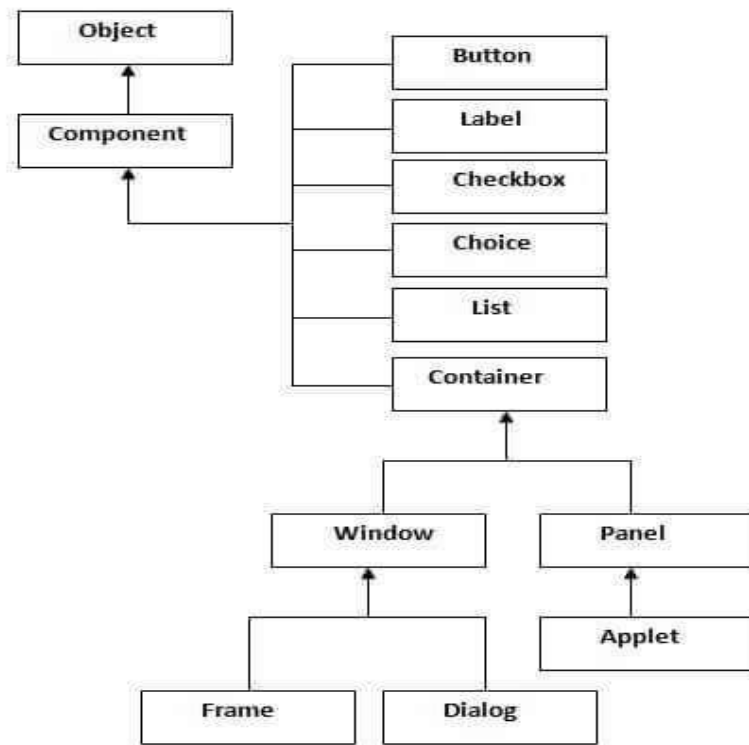

The window is the container that has no borders and menu bars. You must use frame, dialog or another window for creating a window.

Panel

The Panel is the container that doesn't contain a title bar and menu bars. It can have other components like buttons, textfield etc.

Frame

The Frame is the container that contain title bar and can have menu bars. It can have other components like button, textfield etc

Useful Methods of Component class

Method	Description
public void add(Component c)	inserts a component on this component.
public void setSize(int width,int height)	sets the size (width and height) of the component.
public void setLayout(LayoutManager m)	defines the layout manager for the component.

public void setVisible(boolean status)	changes the visibility of the component, by default false.
--	--

Java Event classes and Listener interfaces

Event Classes	Listener Interfaces
ActionEvent	ActionListener
MouseEvent	MouseListener and MouseMotionListener
MouseWheelEvent	MouseWheelListener
KeyEvent	KeyListener
ItemEvent	ItemListener
TextEvent	TextListener
AdjustmentEvent	AdjustmentListener
WindowEvent	WindowListener
ComponentEvent	ComponentListener
ContainerEvent	ContainerListener
FocusEvent	FocusListener

Window Fundamentals

The AWT defines windows according to a class hierarchy that adds functionality and specificity with each level. The two most common windows are those derived from Panel, which is used by applets, and those derived from Frame, which creates a standard application window. Much of the functionality of these windows is derived from their parent classes. Thus, a description of the class hierarchies relating to these two classes is fundamental to their understanding. Below figure shows the class hierarchy for Panel and

Frame. Let's look at each of these classes now.

Component

At the top of the AWT hierarchy is the Component class. Component is an abstract class that encapsulates all of the attributes of a visual component. All user interface elements that are displayed on the screen and that interact with the user are subclasses of Component. It defines over a hundred public methods that are responsible for managing events, such as mouse and keyboard input, positioning and sizing the window, and repainting. A Component object is responsible for remembering the current foreground and background colors and the currently selected text font.

Container

The Container class is a subclass of Component. It has additional methods that allow other Component objects to be nested within it. Other Container objects can be stored inside of a Container (since they are themselves instances of Component). This makes for a multileveled containment system. A container is responsible for laying out (that is, positioning) any components that it contains..

Panel

The Panel class is a concrete subclass of Container. It doesn't add any new methods; it simply implements Container. A Panel may be thought of as a recursively nestable, concrete screen component. Panel is the superclass for Applet. When screen output is directed to an applet, it is drawn on the surface of a Panel object. In essence, a Panel is a window that does not contain a title bar, menu bar, or border. This is why you don't see these items when an applet is run inside a browser. When you run an applet using an applet viewer, the applet viewer provides the title and border. Other components can be added to a Panel object by its add() method (inherited from Container). Once these components have been added, you can position and resize them manually using the setLocation(), setSize(), setPreferredSize(), or setBounds() methods defined by Component.

Window

The Window class creates a top-level window. A top-level window is not contained within any other object; it sits directly on the desktop. Generally, you won't create Window objects directly. Instead, you will use a subclass of Window called Frame, described next.

Frame

Frame encapsulates what is commonly thought of as a “window.” It is a subclass of `Window` and has a title bar, menu bar, borders, and resizing corners. If you create a `Frame` object from within an applet, it will contain a warning message, such as “Java Applet Window,” to the user that an applet window has been created. This message warns users that the window they see was started by an applet and not by software running on their computer. When a `Frame` window is created by a stand-alone application rather than an applet, a normal window is created.

Canvas

Although it is not part of the hierarchy for applet or frame windows, there is one other type of window that you will find valuable: `Canvas`. `Canvas` encapsulates a blank window upon which you can draw.

Working with Frame Windows

After the applet, the type of window you will most often create is derived from `Frame`. You will use it to create child windows within applets, and top-level or child windows for stand-alone applications. As mentioned, it creates a standard-style window.

Here are two of `Frame`’s constructors:

-`Frame()`

-`Frame(String title)`

The first form creates a standard window that does not contain a title. The second form creates a window with the title specified by `title`. Notice that you cannot specify the dimensions of the window. Instead, you must set the size of the window after it has been created. There are several key methods you will use when working with `Frame` windows. They are examined here

Setting the Window’s Dimensions

The `setSize()` method is used to set the dimensions of the window. Its signature is shown

here: `void setSize(int newWidth, int newHeight)` `void setSize(Dimension newSize)`

The new size of the window is specified by `newWidth` and `newHeight`, or by the width and height fields of the `Dimension` object passed in `newSize`. The dimensions are specified in terms of pixels. The `getSize()` method is used to obtain the current size of a window. Its signature is shown here: **`Dimension getSize()`** -This method returns the current size of the window contained within the width and height fields of a `Dimension` object.

Hiding a Window

After a frame window has been created, it will not be visible until you call `setVisible()`. Its signature is shown here: `void setVisible(boolean visibleFlag)`. The component is visible if the argument to this method is true. Otherwise, it is hidden.

Setting a Window’s Title

You can change the title in a frame window using `setTitle()`, which has this general form: `void setTitle(String newTitle)` Here, `newTitle` is the new title for the window.

Closing a Frame Window

When using a frame window, your program must remove that window from the screen when it is closed, by calling `setVisible(false)`. To intercept a window-close event, you must implement the `windowClosing()` method of the `WindowListener` interface. Inside `windowClosing()`, you must remove the window from the screen. The example in the next section illustrates this technique.

Control Fundamentals

The AWT supports the following types of controls:

- Labels
- Push buttons
- Check boxes
- Choice lists
- Lists
- Scroll bars
- Text editing

These controls are subclasses of `Component`

Adding and Removing Controls

To include a control in a window, you must add it to the window. To do this, you must first create an instance of the desired control and then add it to a window by calling `add()`, which is defined by `Container`. The `add()` method has several forms. The following form is the one that is used for the first part of this chapter:

Component add(Component compObj)

Here, `compObj` is an instance of the control that you want to add. A reference to `compObj` is returned. Once a control has been added, it will automatically be visible whenever its parent window is displayed. Sometimes you will want to remove a control from a window when the control is no longer needed. To do this, call `remove()`. This method is also defined by `Container`. It has this general form:

```
void remove(Component obj)
```

Here, `obj` is a reference to the control you want to remove. You can remove all controls by calling `removeAll()`.

Responding to Controls

Except for labels, which are passive, all controls generate events when they are accessed by the user. For example, when the user clicks on a push button, an event is sent that identifies the push button. In general, your program simply implements the appropriate interface and then registers an event listener for each control that you need to monitor. Once a listener has been installed, events are automatically sent to it

The HeadlessException

Most of the AWT controls described in this practical now have constructors that can throw a `HeadlessException` when an attempt is made to instantiate a GUI component in a non-interactive environment (such as one in which no display, mouse, or keyboard is present). The `HeadlessException` was added by Java 1.4. You can use this exception to write code that can adapt to non-interactive environments. (Of course, this is not always possible.)

Using Buttons

Perhaps the most widely used control is the push button. A push button is a component that contains a label and that generates an event when it is pressed. Push buttons are objects of type `Button`. `Button` defines these two constructors:

`Button()` throws `HeadlessException` `Button(String str)` throws `HeadlessException`

The first version creates an empty button. The second creates a button that contains `str` as a label. After a button has been created, you can set its label by calling `setLabel()`. You can retrieve its label by calling `getLabel()`. These methods are as follows: `void setLabel(String str)` `String getLabel()` Here, `str` becomes the new label for the button

Handling Buttons

Each time a button is pressed, an action event is generated. This is sent to any listeners that previously registered an interest in receiving action event notifications from that component. Each listener implements the `ActionListener` interface. That interface defines the `actionPerformed()` method, which is called when an event occurs. An `ActionEvent` object is supplied as the argument to this method. It contains both a reference to the button that generated the event and a reference to the action command string associated with the button.

By default, the action command string is the label of the button. Usually, either the button reference or the action command string can be used to identify the button. Here is an example that creates three buttons labeled “Yes”, “No”, and “Undecided”

Each time one is pressed, a message is displayed that reports which button has been pressed. In this version, the action command of the button (which, by default, is its label) is used to determine which button has been pressed. The label is obtained by calling the `getActionCommand()` method on the `ActionEvent` object passed to `actionPerformed()`.

```
/ Demonstrate Buttons
import java.awt.*;
import java.awt.event.*;
import java.applet.*;
/*
<applet code="ButtonDemo" width=250 height=150>
</applet> */
public class ButtonDemo extends Applet implements ActionListener {
    String msg = ""; Button yes, no,
    maybe; public void init() { yes =
    new Button("Yes"); no = new
    Button("No"); maybe = new
    Button("Undecided");
    add(yes);
    add(no);
    add(maybe);
```

```

yes.addActionListener(this);
no.addActionListener(this);
maybe.addActionListener(this);
}
public void actionPerformed(ActionEvent ae)
{
String str = ae.getActionCommand();
if(str.equals("Yes"))
{ msg = "You pressed
Yes.";
}
else if(str.equals("No"))
{ msg = "You pressed
No.";
}
else {
msg = "You pressed Undecided.";
}
repaint();
}
public void paint(Graphics g) {
g.drawString(msg, 6, 100);
}
}

```

Sample output from the ButtonDemo program is shown below

As mentioned, in addition to comparing button action command strings, you can also determine which button has been pressed, by comparing the object obtained from the getSource() method to the button objects that you added to the window. To do this, you must keep a list of the objects when they are added.

Program:

```

import java.awt.*;
import javax.swing.*;
import java.awt.event.*;
import java.applet.*;

public class BankForm extends JFrame implements ActionListener
{
    Label title = new Label("BANK OF JALGAON");
    Label name= new Label("Name:");
    TextField name1= new TextField();
    Label aadhar= new Label("Aadhar No:");
    TextField aadhar1= new TextField();
    Label address= new Label("Address:");

```

```

TextField address1= new TextField();
Label city= new Label("City:");
TextField city1= new TextField();
Label state= new Label("State:");
TextField state1= new TextField();
Label country= new Label("Country:");
TextField country1= new TextField();
Label mob= new Label("Mobile No:");
TextField mob1= new TextField();

        String s3= state1.getText();
        String s4= country1.getText();
        //int s9= aadhar1.getText();

        int n1= checkInput(s1);
        int n2= checkInput(s2);
        int n3= checkInput(s3);
        int n4= checkInput(s4);
        //int n9= checkInput(s9);

        if(n1==1)
        {
            JOptionPane.showMessageDialog(save,"Please Enter Valid Name");
            name1.setText("");
            return(false);
        }

        if(n2==1)
        {
            JOptionPane.showMessageDialog(save,"Please Enter Valid city");
            city1.setText("");
            return(false);
        }
    }

```

```

        if(n3==1)
        {
            JOptionPane.showMessageDialog(save,"Please Enter Valid State");
            state1.setText("");
            return(false);
        }

        if(n4==1)
        {
            JOptionPane.showMessageDialog(save,"Please Enter Valid country");
            country1.setText("");
            return(false);
        }

        return(false);
    }

    public static void main(String args[])
    {
        BankForm f= new BankForm();
        f.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
        f.setVisible(true);
    }
}

```

Conclusion:

With the help of the awt we are creating the Bank form which takes the credentials and Main task was to check for the Validation from the user like Adhaar number should be of 12 digits only,the email must include @ sign in it .

Name and Sign of Teacher
